#### Abstract

Two new compounds, (E)-2-(3-ethoxy-2-hydroxybenzylidene)hydrazinecarbothioamide (1) and $(E)$ - $N$-ethyl-2-((2-hydroxynaphthalen-1-yl)methylene)hydrazinecarbothioamide (2) have been synthesized. The prepared compounds have been characterized by CHN analysis, FT-IR, UV-Vis, ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectroscopic techniques as well as the fluorescence emission spectroscopy. The molecular structures of the compounds have also been determined by X-ray single crystal diffraction analysis. The crystal structures revealed that the compounds are remain as a thione form in the solid state and are different in their geometrical, conformational and symmetrical structures. The nuclease activity of compounds to cleave pBR 322 has been investigated using agarose gel electrophoresis assay. The compound 2 revealed a significant nuclease activity which was attributed to the lipophilic properties that provided by substituent moieties of the compound.

## 1. Introduction

Thiosemicarbazones have received more attention due to their chemotherapeutic applications [1-4]. Thiosemicarbazones are important compounds because of their antiviral, antimalarial, antifungal and antitumor activities [59]. The biological activity of thiosemicarbazones are a function for their aldehyde or ketone moiety, which acts as a tridentate ONS donor ligands and provide a suitable complexation structure for many transition metals [10-14]. Thiosemicarbazones ligands attract considerable attention because they are straightforward to synthesize and have scope for structural diversity $[15,16]$. Recent studies showed the biological activities of thiosemicarbazones especially the antitumor activity are a function of their geometrical and conformational structures, the most active thiosecarbazones are that possess the trans isomer [17-20]. The ability of compounds to cleave DNA has received more attention because of such compounds can be used as agents in biotechnology, structural studies of nucleic acids, or development of new drugs [21-23]. Thiosecarbazones are one of a suitable chelating agents for metal ions which can be using as artificial nucleases because of their various structural features
and their ability to change their redox potential during coordinated with these ligands $[24,25]$.

To our best knowledge, there is still very little information available regarding the DNA cleavage by thiosemicarbazones. Here, we present the synthesis, spectral characterization, X-ray single crystal structure and nuclease activity to cleave pBR 322 plasmid DNA for two new thiosemicarbazone compounds.

## 2. Experimental

### 2.1. Materials and methods

All the reagents and solvents were purchased from SigmaAldrich were of reagent grade and used without further purification. Melting point was measured by the Stuart Scientific SMP1 melting point apparatus. FT-IR spectra were recorded on a Perkin Elmer System 2000 spectrophotometer using the KBr disc method. UV-Visible spectra were recorded on a Perkin Elmer Lambda-35 spectrophotometer. Fluorescence spectra were recorded on a Jasco FP-750 spectrophotometer. ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Bruker 500 MHz using DMSO- $d_{6}$ as the solvent. The chemical shift values are reported in ppm from TMS.

Scheme 1

Scheme 2

Elemental analysis was conducted using a Perkin Elmer 2400 Series- 11 CHN analyzer. X-ray crystallographic data were recorded on a Bruker SMART APEXII CCD area-detector diffractometer using graphite monochromated $\mathrm{MoK} \alpha$ radiation ( $\lambda=0.71073 \AA$ ) at 100 K . The data were collected and reduced using APEX2 and SAINT programs. The structure of all compounds was solved using the SHELXS-97 program package, and refined using the SHELXL-97 program package. All non-hydrogen atoms were anisotropically refined. The molecular graphics were created using SHELXTL-97 [26].

### 2.2. Nuclease activity assay

The nuclease activity of compound 1 and 2 to cleave pBR322 plasmid DNA was studied using agarose gel electrophoresis technique in Tris/EDTA buffer solution. The samples were prepared by mixing appropriate quantities from DNA, compound and $\mathrm{H}_{2} \mathrm{O}_{2}$. Then incubated at $37^{\circ} \mathrm{C}$ for 2 h , treated with loading dye, and electrophoresed for 1 h at 50 V on $1 \%$ agarose gel consisting of 12 lanes: lane 1, pBR322 DNA $(0.025 \mu \mathrm{M})$; lane 2, DNA $(0.025 \mu \mathrm{M})+$ compound $(6 \mu \mathrm{M})$; lane 3, DNA $(0.025 \mu \mathrm{M})+\mathrm{H}_{2} \mathrm{O}_{2}(4.5 \mu \mathrm{M})$; lane 4, DNA $(0.025 \mu \mathrm{M})+$ $\mathrm{H}_{2} \mathrm{O}_{2}(4.5 \mu \mathrm{M})+$ compound $(1 \mu \mathrm{M})$; lane 5, DNA $(0.025 \mu \mathrm{M})+$ $\mathrm{H}_{2} \mathrm{O}_{2}(4.5 \mu \mathrm{M})+$ compound $(2 \mu \mathrm{M})$; lane 6, DNA $(0.025 \mu \mathrm{M})+$ $\mathrm{H}_{2} \mathrm{O}_{2}(4.5 \mu \mathrm{M})+$ compound $(3 \mu \mathrm{M})$; lane 7, DNA $(0.025 \mu \mathrm{M})+$ $\mathrm{H}_{2} \mathrm{O}_{2}(4.5 \mu \mathrm{M})+$ compound $(3.5 \mu \mathrm{M})$; lane 8, DNA $(0.025 \mu \mathrm{M})+$ $\mathrm{H}_{2} \mathrm{O}_{2}(4.5 \mu \mathrm{M})+$ compound $(4 \mu \mathrm{M})$; lane 9, DNA $(0.025 \mu \mathrm{M})+$ $\mathrm{H}_{2} \mathrm{O}_{2}(4.5 \mu \mathrm{M})+$ compound $(4.5 \mu \mathrm{M})$; lane 10 , DNA $(0.025 \mu \mathrm{M})$ $+\mathrm{H}_{2} \mathrm{O}_{2}(4.5 \mu \mathrm{M})+$ compound $(5 \mu \mathrm{M})$ and lane 11, DNA ( 0.025 $\mu \mathrm{M})+\mathrm{H}_{2} \mathrm{O}_{2}(4.5 \mu \mathrm{M})+$ compound $(6 \mu \mathrm{M})$. The gel was then stained with ethidium bromide before being photographed under UV light. The results were controlled using 1 kbp ladder DNA (lane, L).

### 2.3. General procedure for the synthesis of compound 1 and 2

A solution of the corresponding aldehyde in ethanol (20 mL ) was added to an ethanolic solution (20 mL) of thiosemicarbazide ( 5.48 mmol ) or 4-ethyl-3-thiosemicarbazide ( 4.19 mmol ). The resulting yellow solution was refluxed with stirring for 2 h (Scheme 1). The product was isolated by filtration, washed with ethanol and dried. Plate colorless and needle yellow were obtained by slow evaporation of DMF for compound 1 and 2, respectively.

## 3. Results and discussion

### 3.1. Synthesis

The (E)-2-(3-ethoxy-2-hydroxybenzylidene)hydrazine carbothioamide (1) and ( $E$ )- N -ethyl-2-((2-hydroxynaphthalen-1-yl)methylene)hydrazinecarbothioamide (2) were prepared by the condensation reaction of 3-ethoxy-2-hydroxybenzaldehyde and thiosemicarbazide or 2-hydroxy-1-naphthaldehyde and 4-ethyl-3-thiosemicarbazide (Scheme 1). The compounds may exist in two tautomeric forms, either thione or thiol form (Scheme 2). The compounds are air stable and soluble in DMF, DMSO, and rare soluble in $\mathrm{H}_{2} \mathrm{O}$.

### 3.2. FT-IR analysis

The bands appeared at 3405 and $3149 \mathrm{~cm}^{-1}$ are attributed to the $v(\mathrm{OH})$ and $v(\mathrm{~N}-\mathrm{NH})$ for compound 2, respectively. The imino group ( $\mathrm{C}=\mathrm{N}$ ) for compound 2 gave a band at 1600-1609 $\mathrm{cm}^{-1}$. The strong band observed at 1550 and $1537 \mathrm{~cm}^{-1}$ is attributed to $v\left(\mathrm{C}_{\text {aro }} 0\right)$ for compound $\mathbf{1}$ and 2, respectively. The
thione group ( $\mathrm{C}=\mathrm{S}$ ) for compound $\mathbf{1}$ and $\mathbf{2}$ gave a sharp stretching band at 1275 and $1264 \mathrm{~cm}^{-1}$, respectively.

## 3.3. ${ }^{1}$ H NMR analysis

The ${ }^{1} \mathrm{H}$ NMR spectra of compound $\mathbf{1}$ and $\mathbf{2}$ are shown in Figure 1 and 2, respectively. In compound 1, the triplet signal at $\delta 1.37 \mathrm{ppm}$ is attributed to $\mathrm{CH}_{3}$ protons, the quartet signal at $\delta 4.04 \mathrm{ppm}$ is attributed to $\mathrm{CH}_{2}$ protons. The interaction between the aromatic protons produces triplet signal for $\mathrm{C}_{5}-\mathrm{H}$ at $\delta 6.57 \mathrm{ppm}$, and doublet signals for $\mathrm{C}_{4}-\mathrm{H}$ and $\mathrm{C}_{6}-\mathrm{H}$ at $\delta 6.91$ and 7.50 ppm , respectively. The singlet signals at $\delta 7.87$ and 8.03 ppm are attributed to $\mathrm{NH}_{2}$ protons. The OH proton show a broad signal at $\delta 9.13 \mathrm{ppm}$, whereas the observed singlet signals at $\delta 8.41$ and 11.40 ppm are attributed to the $\mathrm{CH}=\mathrm{N}$ and N -NH protons.

Figure 1. ${ }^{1} \mathrm{H}$ NMR spectrum of compound 1 in DMSO- $d_{6}$.

Figure 2. ${ }^{1} \mathrm{H}$ NMR spectrum of compound 2 in DMSO- $d_{6}$.
In compound 2, the triplet signal at $\delta 1.18 \mathrm{ppm}$ is attributed to $\mathrm{CH}_{3}$ protons, the quintet signal at $\delta 3.62 \mathrm{ppm}$ is attributed to $\mathrm{CH}_{2}$ protons resulting from the interaction with $\mathrm{CH}_{3}$ and NH protons. The interaction between the aromatic protons produces doublet signal at $\delta 7.22 \mathrm{ppm}$ for $\mathrm{C}_{5}-\mathrm{H}$, triplet signals at $\delta 7.39$ and 7.57 ppm for $\mathrm{C}_{6}-\mathrm{H}$ and $\mathrm{C}_{7}-\mathrm{H}$, respectively, the interaction of $\mathrm{C}_{3}-\mathrm{H}$ and $\mathrm{C}_{4}-\mathrm{H}$ results a doublet of doublet signal at $\delta 7.85 \mathrm{ppm}$, whereas the $\mathrm{C}_{8}-\mathrm{H}$ show a doublet signal at $\delta 8.46 \mathrm{ppm}$. The broad triplet signal that emerged at $\delta 8.38$ ppm is attributed to $\mathrm{CS}-\mathrm{NH}$ proton, the nuclear quadrupole interaction of ${ }^{14} \mathrm{~N}(I=1)$ causes to lower the lifetime of excited state of the protons which leads to broaden the resulting NMR signal. The $\mathrm{CH}=\mathrm{N}$ proton appeared as a singlet signal at $\delta 9.06$ ppm.

## 3.4. ${ }^{13}$ C NMR analysis

Both the compounds 1 and 2 show the carbon signal of $\mathrm{CH}_{3}$ at $\delta 14.50 \mathrm{ppm}$. The oxygen atom shifted the carbon signal of $\mathrm{CH}_{2}$ to downfield more than nitrogen atom which shown at $\delta 64.15$ and 30.62 ppm for compound 1 and 2, respectively. The aromatic carbons of compound 1 appeared in the range from $\delta 114.06$ to 146.17 ppm , whereas for compound 2 from $\delta$ 109.77 to 142.61 ppm . The signal at $\delta 177.51 \mathrm{ppm}$ is attributed to the carbon of $\mathrm{C}=\mathrm{S}$ and, the carbon signals of $\mathrm{C}=\mathrm{N}$ are appeared at $\delta 146.95 \mathrm{ppm}$ for compound 1.

### 3.5. UV-Visible analysis

The electronic transition spectra of compound 1 and 2 shown in Figure 3, were measured in DMSO at room temperature. The compound 1 show two absorption bands at 295 and 312 nm which are attributed to the $\pi \rightarrow \pi^{*}$ transition of aromatic ring and $n \rightarrow \pi^{*}$ transition of the azomethine and thiolate function, respectively. The compound 2 show three absorption bands at 320 and 330 nm which are attributed to $\pi \rightarrow \pi^{*}$ transition, and at 370 nm which attributed to $\mathrm{n} \rightarrow \pi^{*}$ transition.

Figure 3. Electronic transitions of the compounds 1 and 2.

### 3.6. Fluorescence analysis

The fluorescence emission spectra of compound 1 and 2 shown in Figure 4, were measured in DMSO at room temperature. The fluorescence emission is attributed to the $\pi^{*} \rightarrow \pi$ transition rather than the $\pi^{*} \rightarrow \mathrm{n}$ transition because the quantum efficiency is greater and the lifetime is shorter than that for the $\pi^{*} \rightarrow \mathrm{n}$ transition [27]. The compounds 1 and 2 show a fluorescence emission bands at 378 nm . The compound 1 show second emission band at 520 nm may be due to formation of excimer molecule, which is arises when the rigidity and steric features succeed to bring the molecules close enough to limit that allows to energy transfer which leads to generate an excimer molecule [28].

### 3.7. X-ray crystallography diffraction analysis

The crystal data and refinement parameters for compounds $\mathbf{1}$ and 2 are summarized in Table 1. The bond lengths $(\AA)$, bond angles $\left({ }^{\circ}\right)$ and torsion angles $\left({ }^{\circ}\right)$ are given in Table 2 , 3 and 4, respectively. The molecular structures are shown in Figure 5 and 6, respectively.

The compound $\mathbf{1}$ is a second monoclinic $\left(\mathrm{P} 2_{1} / \mathrm{c}\right)$ and is close to the molecule B of the previously reported ( $\mathrm{P} 2_{1}$ ) form, which was isolated from an ethanol solution [29]. To a first approximation, the molecular structure found is similar, but three significant differences are noted.

Table 1. Crystal data and refinement parameters for compounds 1 and 2.

| Parameter | Compound 1 | Compound 2 |

Figure 4. Fluorescence emission spectra of the compounds $\mathbf{1}$ and 2.

Figure 5. Molecular structure of compound 1.
In addition, the compound $\mathbf{1}$ show the anti configuration of C3 atom with respect to C6 atom (torsion angle: C3-C4-C5-C6 $\left.=-0.7(2)^{\circ}\right)$, whereas the corresponding atoms of molecule B show the syn configuration (torsion angle: C13-C14-C15-C16 = $\left.1.2(8)^{\circ}\right)$. Moreover, the value of $\beta$ angle in the $\mathrm{P}_{2} / \mathrm{c}$ form is $100.494(2)^{\circ}$, whereas that for the reported $\mathrm{P} 2_{1}$ is close to $90^{\circ}$ and equal to $90.238(3)^{\circ}$. A significant difference arises from the calculated refinement parameters of $\mathrm{R}_{1}, w \mathrm{R}_{2}$ and S , which are $0.0478,0.1025$ and 1.04 ; and $0.056,0.119$ and 0.92 , for $\mathrm{P} 2_{1} / \mathrm{c}$ and $\mathrm{P} 2_{1}$, respectively. Furthermore, the compound $\mathbf{1}$ in
$\mathrm{P} 2_{1}$ /c form is centrosymmetric, whereas the $\mathrm{P} 2_{1}$ form is noncentrosymmetric [30].

Figure 6. Molecular structure of compound 2.
The prepared compounds show different structures based on the geometry of N 1 atom in relation to C 1 atom and C 5 or C9 atom. In compound 1, the N1 atom shows the trans geometry in relation to C 1 atom and the cis geometry in relation to C5 atom. These geometries prevent the formation of intrahydrogen bonding of $01-\mathrm{H} \cdots \mathrm{N} 1$. Whereas, in compound 2, the N 1 show the cis geometry in relation to C 1 atom and the trans geometry in relation to the corresponding of C9 atom. These geometries allow the formation of intrahydrogen bonding of $01-\mathrm{H} \cdots \mathrm{N} 1$. Both the compounds the N 1 atom shows the cis geometry in relation to N3 atom and the trans geometry in relation to S1 atom. The bond distances of S1-C and C-N2 are $1.7015(18)$ and $1.347(2) \AA$ and, 1.6854 (19) and 1.357(3) $\AA$, respectively. These distances confirmed that the compounds exist in thione form in sold state, which are changes upon complexation to thiol form [31].

Moreover, the compound $\mathbf{1}$ in monoclinic $\mathrm{P}_{1} / \mathrm{c}$ crystal system with the presence of inversion center is centrosymmetric as shown in Figure 7, and show three planes. The first plane includes $\mathrm{N} 1-\mathrm{N} 3, \mathrm{C} 8$ and S 1 , the second plane includes 01, C1, C2 and C5-C7 and the third plane includes C3, C4, O2, C9 and C10. The dihedral angles between the first and second planes is $176.36(14)^{\circ}$, and between the second and third planes is $172.11(13)^{\circ}$. By contrast, the compound 2 in
monoclinic $\mathrm{P} 2_{1}$ crystal system with the absence of inversion center is non-centrosymmetric as shown in Figure 8, and show two planes. The first plane includes the aromatic rings and C 11 , and the second plane includes $\mathrm{N} 1-\mathrm{N} 3,01, \mathrm{~S} 1$ and C12C14. The dihedral angle between the two planes is -179.77 (17) ${ }^{\circ}$.

Figure 7. Crystal structure planes of compound 1.

Figure 8. Crystal structure planes of compound 2.
The crystal structure of compound $\mathbf{1}$ molecules form centrosymmetrically related dimmers through the intermolecular hydrogen bonds $\mathrm{N} 2-\mathrm{H} 1 \cdots 01$ and $\mathrm{O} 1-\mathrm{H} 1 \cdots \mathrm{~S} 1$ (symmetry code: $-x,-y,-z$ ), and N3-H $\cdots$ S1 (symmetry code: $1-x$, $-y,-z$ ). These hydrogen bonds are stabilizing the packing of the compound 1 molecule in crystal lattice (Figure 9). By contrast, the crystal structure of compound 2 molecules form centrosymmetrically related dimmers through the intermolecular hydrogen bonds $\mathrm{N} 2-\mathrm{H} 1 \cdots \mathrm{~S} 1$ and $\mathrm{C} 11-\mathrm{H} 11 \mathrm{~A} \cdots \mathrm{~S} 1$ (symmetry code: $1-x,-1 / 2+y, 1-z$ ), and C2-H2A $\cdots 01$ (symmetry code: $1-x$, $-1 / 2+y, 2-z$ ). These hydrogen bonds allow the compound 2 molecules to be stacked along the $b$-axis via $\pi-\pi$ interactions which are stabilize the packing crystal structure of the compound. Moreover, the orientation of the phenyl rings (torsion angle $\mathrm{C} 1-\mathrm{C} 10-\mathrm{C} 11-\mathrm{N} 1=-0.2(3)^{\circ}$ ) is stabilized by $01-$ $\mathrm{H} 1 \cdots \mathrm{~N} 1$ hydrogen bond, and the syn conformation of the C13 atom in respect to S 1 atom (torsion angle C13-N3-C12-S1 = $0.1(3)^{\circ}$ ) is stabilized by $\mathrm{N} 3-\mathrm{H} 1 \cdots \mathrm{~N} 1$ hydrogen bond (Figure 10).

### 3.8. DNA cleavage activity

The agarose gel electrophoresis patterns of the compounds 1 and 2 are shown in Figure 11. From lane 1 to 8, the compound 1 show the naturally fast migration form which is related to the closed circular supercoiled form (SC, form I). At concentration $4.5 \mu \mathrm{M}$ (lane 9) and $5.0 \mu \mathrm{M}$ (lane 10), the compound show the slow migration form which is related to the open circular relaxed form (OC, form II) [32]. Whereas, the compound 2 show higher cleavage activity, it can nick one of the DNA strands to produce the OC form at concentration $1 \mu \mathrm{M}$
(lane 4). The presence of terminal $N(4)$-ethyl and groups are increase the lipophilic properties of compound 2 which are increase the affinity with the hydrophobic medium of DNA together with the geometrical and conformational structures that may be lead to an intimate association with DNA, which in turn increases the action of compound to cleave DNA. The compounds show different action regarding the SC form. In compound 1, the size of SC fragments increases with increase the concentration of the compound, whereas for compound 2 the size of SC fragments decreases with increase the concentration of the compound. Furthermore, the addition of 6 $\mu \mathrm{M}$ of both compounds (lane 11) to DNA leads to a rigid product which may refers to denaturation of DNA.

Figure 9. Crystal packing structure of compound 1, viewed along $c$ axis. Hydrogen bonds are shown as dashed lines.

Figure 10. Crystal packing structure of compound 2, viewed along $b$ axis. Hydrogen bonds are shown as dashed lines.

The DNA cleavage study was investigated in the presence of fixed amount $(4.5 \mu \mathrm{M})$ of $\mathrm{H}_{2} \mathrm{O}_{2}$. The cleavage action can not take place in presence of the compound alone (lane 2) or $\mathrm{H}_{2} \mathrm{O}_{2}$ alone (lane 3). Furthermore, the DNA cleavage was investigated in the presence of the hydroxyl radical scavenger DMSO. If the cleavage action depends on the hydroxyl radical, the DMSO leads to inhibit the nuclease activity of the compounds. These observations confirm that cleavage action depends on the concentration of the compounds 1 and 2 but in presence of $\mathrm{H}_{2} \mathrm{O}_{2}$. Our suggestion that the compounds exist in anion form (Scheme 2) in presence of $\mathrm{H}_{2} \mathrm{O}_{2}$, and the compound anion involves a nucleophilic attack at the phosphate backbone of DNA, which subsequent leads to cleave the DNA strand.

Figure 11. Agarose gel electrophoresis patterns of pBR 322 for the compounds 1 and 2.

## 4. Conclusions

Different analytical and spectral methods were used for the characterization of two new thiosemicarbazones derivatives. The X-ray diffraction analysis shows that the compounds possess different geometrical and conformational structures. The nuclease activity of the compounds against pBR 322 circular plasmid DNA was investigated using agarose gel electrophoresis assay. The compound 2 showed higher nuclease activity than compound $\mathbf{1}$.

## Supplementary material

CCDC 953517 and 958081 contain the supplementary data for compound 1 and 2, respectively. These data can be obtained free of charge at http://www.ccdc.cam.ac.uk/ data_request/cif.
